

What is Position in CSS?

-> Position in CSS is used to control where an element should appear on the webpage.

-> Normally, HTML elements come one below another automatically.

-> Using position, we can move elements to different places.

Syntax:

```
selector {  
    position: value;  
}
```

Types of Positions in CSS:

-> There are mainly 5 types of positions:

1. static (default)
2. relative
3. absolute
4. fixed
5. sticky

Helping Properties used with position:

-> These properties help to move elements:

1. top -> Move from top
2. bottom -> Move from bottom
3. left -> Move from left
4. right -> Move from right

1. static Position:

-> static is the default position of every HTML element.

-> Elements stay in their normal place.

-> top, left, right, bottom will NOT work.

-> Syntax: position: static; (default)

2. relative Position:

-> Position relative means element stays in its normal place but we can move with the help of helping properties.

-> It will take the reference from the original or previous position to move.

-> Syntax: position: relative;

3. absolute Position:

-> Position absolute removes the element from normal document flow.

-> The element moves relative to its nearest ancestor or positioned parent.

-> A positioned parent means parent should have position:relative; value.

-> Syntax: position: absolute;

Note: Whenever we provide `position: absolute` to an HTML element, the element comes to the front because it is removed from the normal document flow. It can overlap other elements.

4. fixed position:

-> The position fixed keeps the element fixed on the screen.

-> Even when scrolling, the element stays in the same place.

-> Mostly used for:

1. Navbar

2. Chat button

2. Back to top button

-> Syntax: position: fixed;

5. sticky position:

-> The position sticky means it works like combination of relative and fixed.

-> Initially behaves like relative.

-> When scrolling reaches a point, it becomes fixed.

-> Mostly used for:

1. Sticky Navbar

2. Sticky table header

-> Syntax: position: sticky;

What is z-index?

-> z-index controls which element appears on top.

-> Basically it controls the stacking order in the z-index for the elements.

-> Works only on positioned elements:

relative

absolute

fixed

sticky

-> Syntax: z-index: value;

Range: $-\infty$ to $+\infty$

-> Higher z-index = appears on top.

Interview Questions:

Q.1 What is difference between relative and absolute position?

Q.2 What is difference between fixed and sticky position?

Q.3 What is z-index Property?
